

# *Motion Capture and Animation using Digital Image Processing*

PRESENTED BY: ELIZA MAE SARET

# *abstract*

We present a practical method for human posture recognition and animation through the use of digital image processing as an alternative for expensive means of motion capture. Given an input video of a moving subject wearing colored markers, the application identifies the position of the body parts and maps its movements into a cartoon character.

# *objectives*

This study aims to create a computer program that can be used to facilitate motion capture and animation by fulfilling the following objectives:

- 01 To use digital image processing and knowledge in human body geometric constraints in detecting and identifying human body parts
- 02 To use the detected human body parts in drawing a moving skeletal figure representing the motion executed
- 03 To map the motions of the moving skeletal figure in animating a character

*date & place of study*

**This study was conducted from January to April, 2018 at the University of the Philippines Los Baños, Institute of Computer Science**

animation

# *materials & methods*

**OpenCV 3.3.0 C++** and **Qt Creator 4.5.1** were used in creating the application. OpenCV C++ was used in preprocessing the input videos, identifying body parts and in creating the character animation. Meanwhile, Qt Creator was used to create the user interface for playing and configuring the animations.

# *setup*

A **mini-studio** was setup in order to produce an input video with colored markers that can easily be recognized by the program. This studio consists of **two small led lights** , a **plain white background** , and a **tripod**. The input video was taken using a **cellphone camera**.

# *preprocessing*

Once the video was loaded into the application, its **contrast, brightness and saturation** were adjusted to allow the application to detect the colored markers better. The frames were also converted from **BGR to HSV colorspace** which is more suitable for color based segmentation.

# *body part identification*

The colors corresponding to the body parts were located in every frame. In order to identify body parts when a single color is used to represent them, it was assumed that the one found at the **upper part** of the frame is either the **hand** or the **elbow** and the one found at the **lower part** is the **leg** or the **foot**.

# *animation*

The characters were drawn using a combination of built-in **drawing functions** in opencv (mostly for the limbs) and **importing images** on detailed body parts. The angle between two endpoints were also taken in order to know how much an image is to be rotated before it is placed in the frame.

Adjust Color HSV Thresholds (0-179, 0-255, 0-255)

	Lower HSV	UPPER HSV
Head	( 170 , 130 , 100 )	( 179 , 255 , 255 )
Neck	( 78 , 140 , 100 )	( 110 , 255 , 255 )
Hips	( 20 , 100 , 100 )	( 60 , 255 , 255 )
Left Hand&Foot	( 45 , 100 , 50 )	( 75 , 255 , 255 )
Left Elbow&Knee	( 0 , 130 , 150 )	( 15 , 255 , 255 )
Right Hand&Foot	( 120 , 100 , 50 )	( 170 , 255 , 180 )
Right Elbow&Knee	( 145 , 40 , 70 )	( 170 , 135 , 255 )

Adjust Input Video

Contrast ☐

Brightness ☒

Saturation ☐

Choose Character

☐ Simple

☒ Mickey Mouse

☐ Morty

☐ Rotate video 90 degrees

*video configuration options*

# *results & discussions*

Three sets of input videos were used to test the ability of the application to detect body movements and animate them.

- dark & inconsistent lighting + valid movements
- balanced light (mini-studio setup) + valid movements
- balanced light + invalid body movements

The set with the inconsistent lighting and the set with invalid movements had more mistakes in body part identification and gave more inaccurate animation as compared to the one taken with balanced lighting and valid movements.

It also took the application a few seconds to a minute to display the outputs depending on the video quality and the length of the input video.

# *conclusion & future work*

- To detect body parts more accurately, it is important to:
  - Consistent amount of light throughout the whole frame
  - Relatively neutral background
  - All markers should be visible in all frames

The output of the demo videos proved that digital image processing can be used as an alternative for expensive means of motion capture based animation.

Other improvements to the application can be done such as:

- Fixing animation when not all markers are visible
- Better human body constraint definition
